

## Mongo DB - week 2

### Creating Documents:

→ Insert one()

→ Insert Many() : Has option to do bulk inserts as well as insert ordering to skip failed records.

→ id field → mongo creates one id field by default (Primary Index) if user has not specified one.

Object Id : DATE | MAC ADDR | PID | COUNTER  
12-BYTE HEX STRING

### Reading Documents:

\* `db.movieDetails.find({rated: "Ph-13"}).count()`  
(Obj) ⇒ 152 records Query Document

`db.movieDetails.find({rated: "Ph-13", Year: 2009}).count()`  
⇒ 8 records.

⇒ `db.movieDetails.find({ "tomato-meter": 100 }).pretty()`  
\* → Nested Document find.

## Findability - matches:

### ① ON Entire Array:

Ex: `db.movieDetails.find({ "writers": ["Ethan Coen", "Joel Coen"] }).count()`  
 \* Here order of element matters.

### ② Based on Any Element:

`db.movieDetails.find({ "actors": "Jeff Bridges" }).pretty()`  
 \* Will match actors having Jeff Bridges in the movie list.

### ③ Based on Specific Element:

Ex: find movies where Jeff Bridges is the main actor  
`db.movieDetails.find({ "actors.0": "Jeff Bridges" }).pretty()`  
 \*  $\rightarrow$  0 means first element in actors array.

\* `find()` method returns a cursor

So: `var c = db.movieDetails.find`

`var doc = function() { return c.hasNext() ?`

`c.objLeftInBatch(); c.next(); null; }`

101

`doc()`  $\rightarrow$  next Element using above function.

Projection: Reduce the size of data returned by a Query. (Limit the fields returned)

Ex: db.movieDetails.find({rated: "PG"},  
{title: 1}).pretty()

Will contain only

\* Explicitly exclude some fields.

{title: 1, \_id: 0}

This will exclude the \_id field in results.

Query Selectors:

\$or, \$gt, \$gte, \$lt, \$lte

Ex: Find all movies having run-time greater than 90.

db.movieDetails.find({runtime: { \$gt: 90 }}).pretty()

\* db.movieDetails.find({runtime: { \$gte: 90, \$lte: 120 }}).  
pretty()

db.movieDetails.find({rated: { \$ne: "UNRATED" }}).count()

db.movieDetails.find({rated: { \$in: ["G", "PG"] }}).pretty()

\$exists, \$type → If a field is of specified type

Ex:

```
db.movieDetails.find( { "tomato.meter" : { $exists : true } } ).count()
```

```
db.movieDetails.find( { "_id" : { $type : "String" } } ).count()
```

Logical Operators:

\$or, \$and, \$not, \$nor (logical NOR returns all documents that fail to match both clauses)

```
db.movieDetails.find( { $or : [ { "tomato.meter" : { $gt : 95 } },  
                                { "metacritic" : { $gt : 88 } } ] } ).pretty()
```

(OR)

```
{ $and : [ { "tomato.meter" : { $gt : 95 } }, -----
```

★ \$and mostly used to specify multiple criteria on same field.

Regex Operators:

```
db.movieDetails.find( { "awards.text" : { $regex : /won.*$/ } }
```

Array Operators:

\$all → matches arrays that contain all elements specified in the array.

Ex:

```
db.movieDetails.find({ genres: { $all: ["comedy", "Crime", "Drama"] } }) .pretty()
```

```
db.movieDetails.find({ countries: { $size: 1 } }) .pretty()
```

\$elemMatch

```
db.movieDetails.find({ boxOffice: { Country: "UK", revenue: { $gt: 15 } } })
```

↓  
This would ~~match~~ <sup>match</sup> the box office element and look for Country UK and revenue greater than 15 in different elements. So use below!

```
db.movieDetails.find({ boxOffice: { $elemMatch: { Country: "UK", revenue: { $gt: 15 } } } })
```

## UPDATING DOCUMENTS

- ① Update One
- ② Update many
- ③ Replace one

db.movieDetails.updateOne ( { title : "The Martian" },  
 { \$set : { poster : "http://..." }

Update field Operators: \$rename, \$set, \$unset

db.movieDetails.updateOne ( { title : "The Martian" },  
 { \$inc : { "tomato.reviews" : 3, "tomato.usersReviews":  
 2533 } }

\* For array field updates use \$push.

\$push along with \$each.

\$slice → keep only these many elements in the array. For example 5 more recent.

\$position → where to push this array element

\* Update many → Update all documents that match the filter.

db.movieDetails.updateMany ( { rated : null },  
 { \$unset : { rated : "" } } )

UPSERTS :  $\rightarrow$  like DB2 merge.

### Mongo DB Schema Design.

$\Rightarrow$  Application Driven Schema : 3<sup>rd</sup> Normal Form.

- \* Rich Documents.
  - \* No Join / Embed Data
  - \* NO Joins in mongo DB (Embed directly)
  - \* No Constraints.
  - \* Atomic Operations
  - \* NO Transaction Support.
  - \* NO Declared Schema.
- \* Avoid constraints & go for embedding data using Collections.
- \* Atomic Operations (ie all or nothing) in mongo DB instead of Transactions.

## One to one Relations

★ Example : Employee  $\leftrightarrow$  Refuse

When to have it in ultimate connection.  
 (ie to embed or not)

- Frequency of Access
- Size of items (mongoDB doc 16MB)
- Atomicity of data

## One to many Relations.

Example : City to Persons.  
 (NY)  $\rightarrow$  (8 million People)

blog Posts : Comments  
 (1) : (10)

(one scenario) Posts

name  
 Comments : [ ]

⇒ one to few scenario.

VS People

{ name : "John"  
 City : "NYC"  
 }  
 and  
 City.  
 { -id : "NYC"  
 }  
 }

## Many to Many Relations:

Ex: Books : Authors

Students : teachers

⇒ Few : few.

### Authors

-id : 27

author\_name : "Mitchel Stark"

books : [12, 7, 8]

### Books.

-id : 12

title : "Gone with the Wind"

## Multi Key Indexed:

### Students

id : 10

name : 'Andrew'

teachers : [1, 7, 10, 23]

### teachers.

id : 10,

name : 'Tony Stark' }

db.Students.find({'teachers': {'\$in': [0, 1]}})

and

db.Students.find({'teachers': {'\$in': [0, 1]}}).explain()

\* Cursor : Btree cursor  
isMultikey : true.

★ What it did while  
the query got executed.

Benefits of Embedding:

- Improved Read Performance
- One Round trip to DB

\* JNF will avoid modification anomalies.

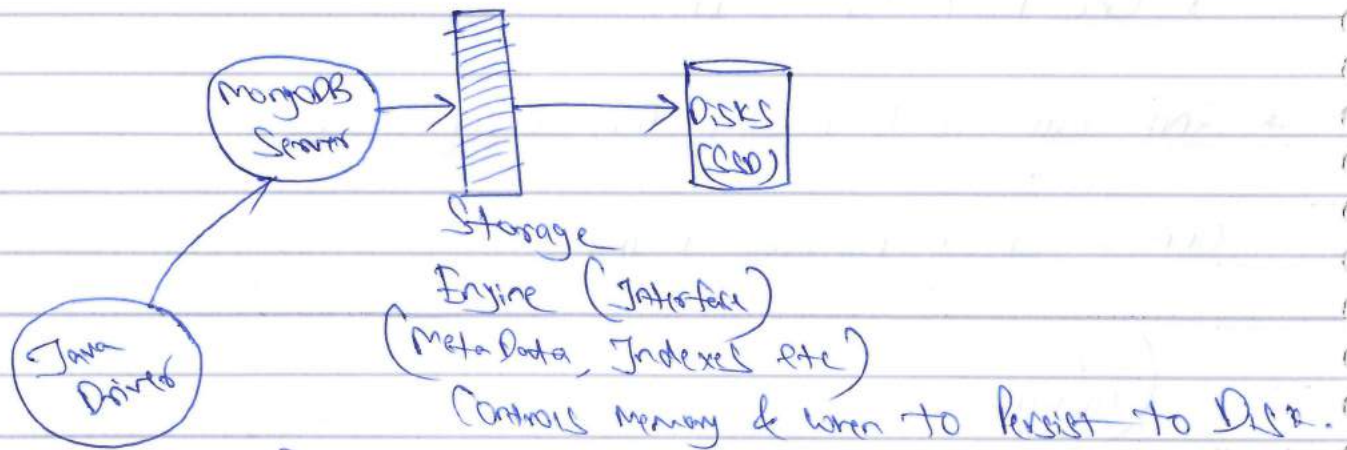

ODM - Object Document Mapper.

\* Morphia → Java ODM for MongoDB.

## Mongo DB (week 4)

→ Pluggable Storage Engines.

Storage Engines:

\* **mmap** → Collection level locking.

\* **Wired Tiger** → Not Default.

!!! \* Offers Document level concurrency.

\* Compression of documents & indexes

\* No Inplace Update

## Index

\* Ordered list of things having pointer to original record on the Disk.

\* BTree implementation.

Writes : Slower  
Reads : Faster } Indexes  
Disadvantage.

db.Students.CreateIndex ( { Student\_id : 13 } ); <sup>Ascending</sup> -1 = Descending.

\* db.Students.explain().find ( { Student\_id : 53 } );  
Query Plan on the Collection followed by the  
Command. And winning Plan can be checked.

\* Explain (true) ⇒ To check how many documents were  
Examined.

db.Students.getIndexes (); ⇒ To check the index on a Collection  
↳ By Default index will be on \_id

db.Students.dropIndex ( { Student\_id : 13 } );

### Multi Key Indexes

Eg:

{ name : 'Andrew',

tags : ['Photography', 'hiking', 'golf'],

Color : 'red',

location : ['NY', 'CA'] }

Index on tags or (tags, color)

But (tags, location) cant be index because both tags & location is an array document.

- Notation & multi key.

\* db.Students.CreateIndex ( { 'scored.score': 1 } );

Unique Indexes:

db.Stuff.CreateIndex ( { thing: 1 }, { "unique": true } );

\* Sparse Indexes  $\rightarrow$  when index key is missing from some of the documents.

For example:

{ a: 1, b: 2, c: 5 }

{ a: 10, b: 5, c: 10 }

{ a: 13, b: 17 }

{ a: 7, b: 23 }

Index on

a  $\rightarrow$  possible

b  $\rightarrow$  possible

c  $\rightarrow$  Not possible since

c value not in some docs.

\* This is when sparse index helps which wont include document 3 and 4 in index since it does not have c value.

⇒ db.employees.createIndex({cell:1}, {unique:true, sparse:true});

Sparse Index → uses collection scan, so don't use for sorting.

### Background Indexes:

db.students.createIndex({score:1}, {background:true});

⇒ Slow

⇒ Don't block readers/writers.

### MongoDB explain:

db.foo.explain().help()

★ var exp = db.example.explain()

helped: exp.help();

exp.find({'a':17, 'b':553}).sort({'b':-1});

### Explain:

- Query Planner (Default)
- Execution Stats
- allPlans Execution

```
var exp = db.example.explain("Execution Stats");  
exp.find({a:17, b:553});
```

- \* Winning Plan + Rejected Plans + Detailed info regarding the several stages of Query execution.

```
var exp = db.example.explain("AllPlans Execution");
```

- \* Execution Stats for All Plans.

⇒ AllPlans Execution array of all Plans.

### Covered Indexes:

```
* exp.find({i:45, j:23}, {_id:0, i:1, j:1, k:1});
```

→ Don't include `_id` in the display.

```
* exp.find({i:45, j:23}, {_id:0});
```

↳ more documents examined all mongo DB

don't know how many more variables are there like `i, j` or `k` etc.

## Choosing an Index:

Example Indexes : ① 

b, c
c, b

 ② 

d, e
e, f

 ⇒ Potential Candidates so three ways plan and check which is fastest.

③ 

a, b, c
---------

⇒ Winning Criteria

① Returned all results

② Threshold Value.

③ Cache winning query.

db.collection.stats()

↳ will give total Index Size()

(or) db.collection.totalIndexSize()

★ So make sure your Indexes fits in the memory.

Threshold comes

Rebuild mongodb restart

## Index Cardinality.

Regular

1:1

Sparse

≤ documents

Multi Key

type: [\_, -, →]

> documents.

## Geo Spatial Indexes.

⇒ Find Things based on location.

i.e Search based on location.

\* db.collection.ensureIndex({location: '2d', type: 1}).  
⇒ 2 Dimensional Index. → Ascending

db.collection.find({location: { \$near: [50, 50] } })  
(or)

db.collection.find({location: { \$near: [50, 50] } }).limit(3)

### Geo Spatial Spherical.

\* 2d Sphere

\* GeoJSON for latitude, longitude coordinates.

db.collection.ensureIndex({location: '2dSphere'})

Example Query:

db.places.find({  
location: {

\$near: {

\$geometry: {

type: "Point",

coordinates: [-122.16, 37.42],

\$maxDistance: 2000 }

} } }

⇓  
for GeoJSON Document  
Index.

Full Text Search.

db.collection.ensureIndex({ 'words': 'text' })

→ text Index. ★★

Example: db.sentences.find({ \$text: { \$search: 'dog' } })

text score ⇒ Document with more word successfully matched.

Ex:

db.sentences.find({ \$text: { \$search: 'dog tree oblidian' },  
\$score: { \$meta: 'text score' } }) .sort({ \$score: { \$meta: 'text score' } })

Designing Using Indexes.

Goal: Efficient Read/Write Operations.

Logging & Profiling:

⇒ logs slow queries by default for query running more than 100ms.

Profiler : Levels

0	1	2
off	log	All my Queries.
	slow queries	

\* db.system.profile.find ( {minis: 2 &gt; 133 } . sort ( {ts: 1 } ) .  
↳ Query which is greater than 1ms pretty(),  
and sorted by time stamp ~~Descending~~.  
Ascending.

→ db.getProfilingLevel() ⇒ To get level of logging.

→ db.setProfiling~~Level~~ level (1, 4)

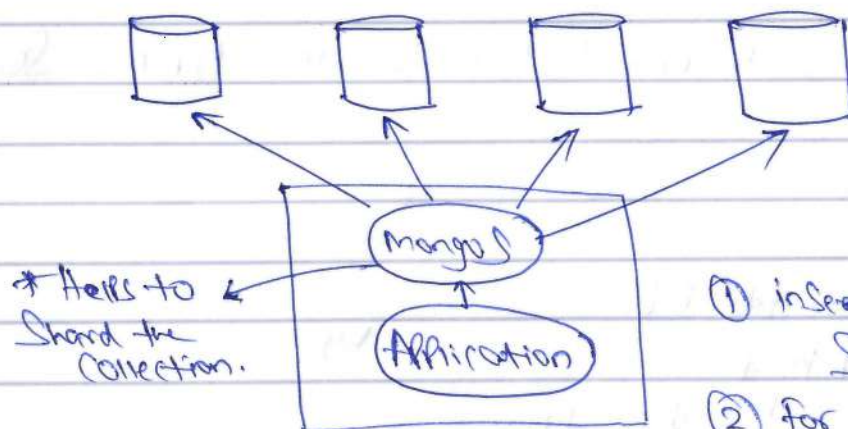

### Mongo top.

\* Mongo DB Profiler, with read & write time information.

mongo stat → What is going on during insert, update, delete queries.

### SHARDING:

⇒ Splitting up large collection among multiple servers.

\* Based on the Query find request to the right server instance.

① insert shard have a Shard key.

② for update / remove / find if Shard key is not there then it finds requests to all servers (i.e. broadcasting)

## Week 5 - Aggregation.

⇒ Similar to Count, Groupby aggregation in RDBMS SQL.

MongoDB Example:

```
db.products.aggregate ([
```

```
  { $group:
```

```
    { _id: "$manufacturer" }
```

```
    , num_products: { $sum: 1 } }
```

```
  ]
```

Aggregation Pipeline:

\$project - reshape a document - 1:1 (one document with one)

\$match - filter stage - 0:1

\$group - aggregate - 0:1 (\$sum or \$count)

\$sort - sort - 1:1

\$skip - skip - 0:1

\$limit - limits - 0:1

\$unwind - Flatten the data

Ex: Initial document tags: ["red", "blue", "green"]

tags: red, tags: blue, tags: green

Compound Grouping:

→ id: { "manufacturer": "\$manufacturer",  
           "category": "\$category" },  
 num\_products: { \$sum: 1 }

★

→ id field can be a document also. and not always a scalar value.

Aggregation Expressions Overview.

\$sum, \$avg, \$min, \$max, \$push, \$addToSet } Push to Array

\$first, \$last } Need to first sort the document otherwise it will be arbitrary.

\$addToSet → Add to collection if its not there.

db.products.aggregate([

{ \$group:

{ \_id: { "maker": "\$manufactures" }

categories: { \$addToSet: "\$category" } }

])

⚡⚡ maker wise find out all the categories.

Double Grouping:

db.fun.find()

{ "\_id": 0, "a": 0, "b": 0, "c": 21 }

{ "\_id": 1, "a": 0, "b": 0, "c": 57 }

.....

db.fun.aggregate([ { \$group: { \_id: { a: "\$a", b: "\$b" },

c: { \$max: "\$c" } } ]

{ \$group: { \_id: "\$\_id.a", c: { \$min: "\$c" } } ] )

\$project:

- remove keys
- Add keys
- Use some simple functions
  - \$toUpper
  - \$toLower
  - \$add
  - \$multiply

Example:

```
db.products.aggregate ( [
```

```
  { $project:
```

```
    { -id: 0 → exclude - id field
```

```
    'maker' : { $toLower: "$manufacturer" },
```

```
    'details' : { 'category' : "$category",
```

```
                'Price' : { $multiply: ["$price", 5]
```

```
            },
```

```
    'item' : { $name: "$_id" } ] ] )
```

\$sort:

⇒ disk & memory based.

→ Default is in-memory based. (100 MB)

⇒ before or after the grouping stage.

### Double Unwind :

- \* → when there are two arrays in a document.
- Can use \$push to reverse the impact of two \$unwinds.

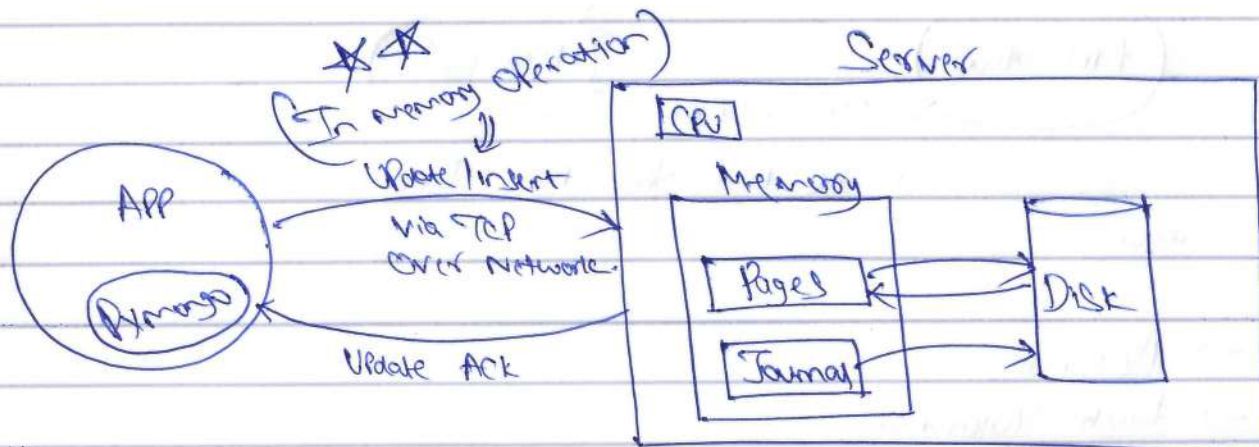

* RDBMS	Mongo DB
WHERE	\$match
HAVING	\$match
SELECT	\$project
ORDER BY	\$sort
SUM()	\$sum
JOIN	mostly using \$unwind.

### Limitations in Aggregation.

- ① 100 MB limit for Pipeline — Use allowDiskUse for this.
- ② 16 MB limit for document size — Use Cursor = 1...3
- ③ Sharded → Group by, Sort will cause it to work on the primary shard and not the replicas hence limiting Scalability when using Aggregation  
⇒ Use Hadoop — Map/Reduce  
Using mongo hadoop connector.

## Week 6

### Write Concern.

\* Updated / Inserts first go and sits in the Pages / Journal area for a while before it goes to disk.

\* Acknowledge →  $\begin{cases} \text{Write} = 1 \\ \text{Journal} = \text{false} \end{cases} \Rightarrow \text{Write Concern.}$

\* If there is a Server Crash and if the Journal Contents were not written to disk, then the data is lost.

w	j
1	false → fast, but small window of vulnerability.
1	True → Slow and can be mentioned @ driver level.

## Network Errors.

When  $w=1$  &  $j=true$

If no ACK then N/w Errors.

## Replication

- Availability
- Fault Tolerance.

- \* If the Primary which went down comes back up, then this will Join as the Secondary node.
- \* Minimum number of nodes is 3, i.e. to have the Election Process.

\* Replication is Asynchronous.

## Types of Replica Set Nodes.

- \* Regular
- \* Arbiter - There for voting purpose
- \* Delayed / Regular - Disaster Recovery node - can't be in voting.  
↳ Cannot be Primary (Priority = 0)
- \* Hidden - Used for Analytics. Priority = 0.

⇒ During Primary Down, no writes allowed.

## Replication Internals.

- \* Write on Primary will give information in Oplog and the Secondary will query this Oplog and apply the same operation on itself.

Oplog: db.oplog.rs.find().pretty();

\* Secondary will have the `Offline` and `OfflineDate` which lets us know the latest update Date/Time.

`OS.getMetrics()`;  $\Rightarrow$  Check `SyncingTo` also.

\*\* If a node comes back up as a Secondary after a period of being Offline and the Oplog has looked / gone ahead on the Primary, then

$\Rightarrow$  The entire data set will be copied from the Primary.

Re-visiting Write Concerns.

`w=1` - wait for Primary to Ack the write

`w=2` - wait for Primary & one other Secondary

`w=3` - ——— & all other Secondary

Write out - How long to wait?

$\rightarrow$  Set on : (1) Connection

(2) on a Collection

(3) Replica Set  $\rightarrow$  Select to do.

`w=majority`  $\rightarrow$  wait for majority of nodes to Ack.

\*\* Journal waits for Primary nodes only.

## Read Preference

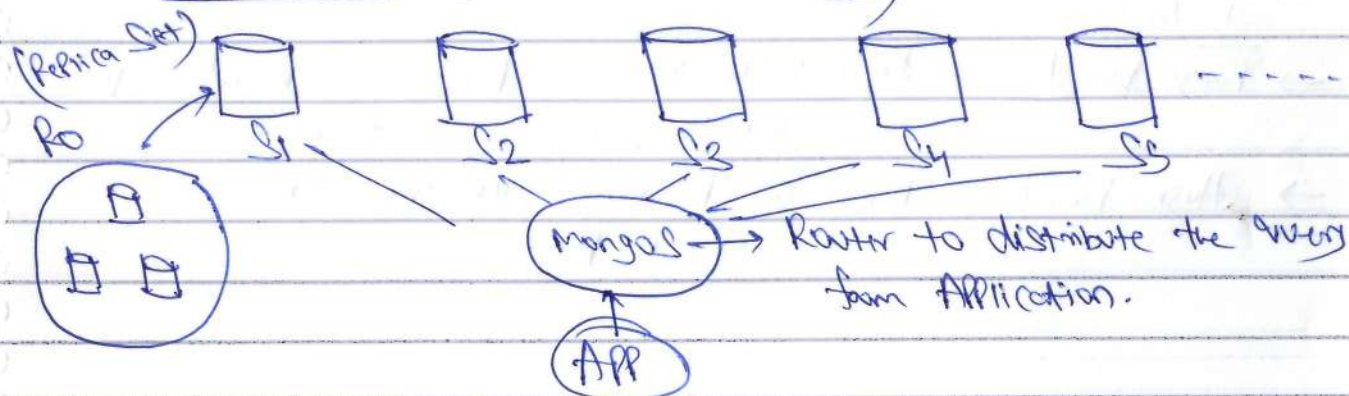

- Default read preference is Primary. To read from Secondary, Use `rs.slaveOk()`.
- Primary preferred - Primary is preferred, if not then
- Eventually Consistent Read.

  - Secondary - Read from Secondary
- Secondary preferred - Secondary is preferred, if not then Primary
- Nearest - Based on min ping time.

## Implication Of Replications:

- \* Seed list - Node should be aware of other nodes
- \* Write Concern - `w & j` Parameters also `wtimeout`
- \* Read Preferences - Since multiple options are there
- \* Errors can happen 🤖 - New errors, Exceptions, Syntax issues etc

## SHARDING (Horizontal Scalability)

\* Break up the Collection into multiple logical parts and have a Shard Key.

→ Range based Sharding

→ Shard Key

Ex: Orders Table

\* Broken into chunks.

\* Need to include Shard Key on inserts.

\* Application Queries the mongo Router which will find out a Particular Shard where the request could be fulfilled.

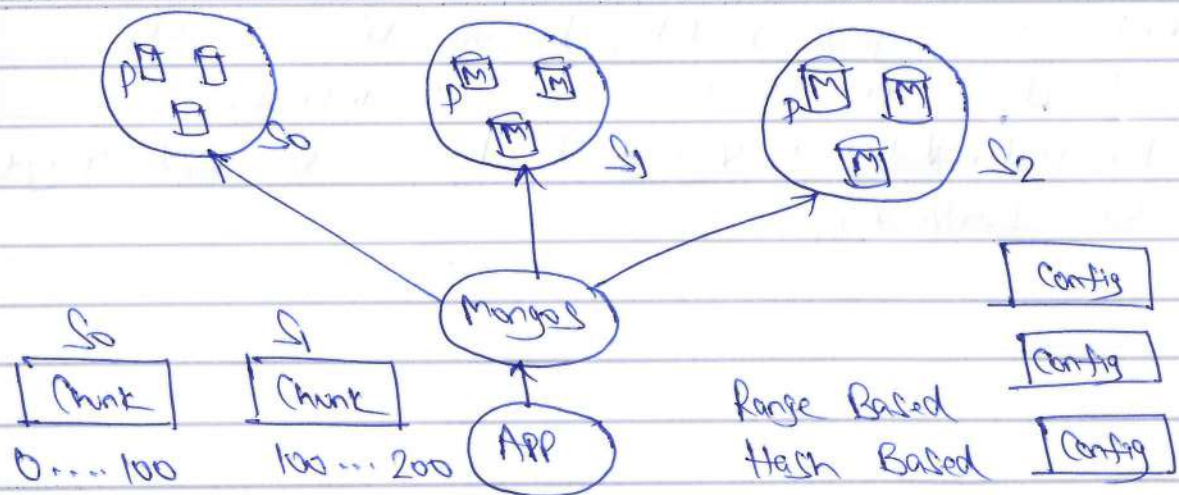

\* Multiple mongos can be present.

\* Each Shard is a replica set again.

Sharding.

→ Range based - Ex: 0 to 100 in Particular shard S<sub>1</sub>  
101 to 200 in S<sub>2</sub> etc.

→ Hash based - Runs a hashing algorithm on the Shard Key.

\* Shard fail over → mongos will try to reconnect.

### Choosing a Shard Key.

\* Sufficient Cardinality — i.e. number of possible values in a column.

\* Avoid Hot Spotting in Writes. i.e. Problem of writes always hitting the same shard because of the shard key. So choose a shard key which is not just increasing in nature but have sufficient cardinality.

Ex: Orders

{ order-id ; —,  
order-date ; —,  
vendor ; — }

- ① Vendor is a good shard key because of Cardinality.
- ② Order-Id is not great as its just increasing.
- ③ (Vendor, Order-date) is very good because of wide range of Cardinality.
